## 1 Inertia Bounds

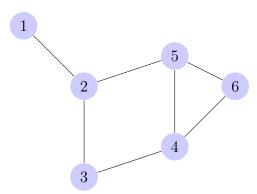

## 1.1 Introduction on Inertia Bounds

#### 1.1 Definition.

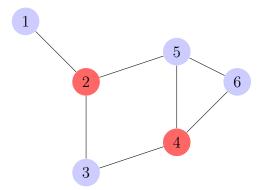

**Independent Set** — An independent set is a set of vertices belonging to a graph in which no two vertices are adjacent.

## 1.1 Example.

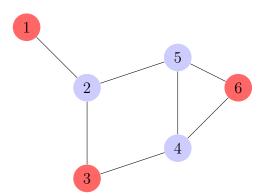

Consider the following graph:

An example of an independent set in this graph is:

However, often the independent set we are most interested in finding is the largest one:

## 1.2 Definition.

**Independence Number** — The independence number of a graph G, denoted  $\alpha(G)$ , is the size of the largest independent set of G.

#### 1.3 Definition.

**Weight Matrix** — The weight matrix of a graph G, is a matrix defined by:

$$W_{i,j} = \begin{cases} c_{i,j} & \text{if } v_i \text{ and } v_j \text{ are adjacent} \\ 0 & \text{otherwise} \end{cases}$$
 (1)

with  $v_i$  a vertice of G and  $c_{i,j}$ , a constant.

The weight matrix of a graph, is identical to an adjacency matrix, except where there was a 1 in the matrix at entry  $A_{i,j}$  if vertices  $v_i$  and  $v_j$  were adjacent, there is now a constant indicating a weighting for the edge between  $v_i$  and  $v_j$ .

For any graph G, there exists a bound on  $\alpha(G)$ , known as the Cvetković bound (also referred to as the Interia Bound). This bound provides a relationship between  $\alpha(G)$  and the number of positive, negative, and zero eigenvalues of the weight matrix, W, associated with G. The Cvetković bound of G, is:

$$\alpha(G) \le \min\{|G| - n_+(W), |G| - n_-(W)\}$$
 (2)

Where  $n_{+}(W)$  and  $n_{-}(W)$  denote the number of positive and negative eigenvalues of W, respectively.

To prove this, we first need to introduce a result that comes from the Eigenvalue Interlacing Theorem:

#### 1.1 Theorem.

Corollary of Eigenvalue Interlacing Theorem — Let A be an  $n \times n$  real symmetric matrix with eigenvalues  $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_n$  and let C be a  $k \times k$  principal submatrix of A with eigenvalues  $\tau_1 \geq \tau_2 \geq \ldots \geq \tau_k$ . Then  $\lambda_i \geq \tau_i$  for all  $i \in \{1, \ldots, k\}$ . [2]

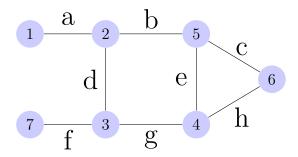

#### 1.4 Definition.

**Principal Submatrix** — The principal submatrix of an  $n \times n$  matrix A is the submatrix obtained where if  $row_i$  is excluded in the submatrix, then  $column_i$  is excluded as well. Note that all principal submatrices of a weight matrix W, correspond to an induced subgraph in the graph represented by W.

#### 1.2 Example.

The following is an example of a principal submatrix in relation to graph theory.

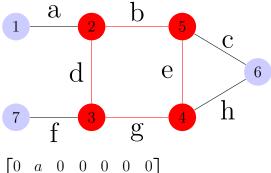

Consider the following graph:

and corresponding weight matrix:

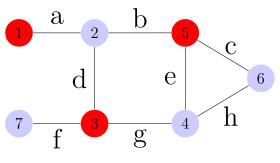

$$\begin{bmatrix} 0 & a & 0 & 0 & 0 & 0 & 0 \\ a & 0 & d & 0 & b & 0 & 0 \\ 0 & d & 0 & g & 0 & 0 & f \\ 0 & 0 & g & 0 & e & h & 0 \\ 0 & b & 0 & e & 0 & c & 0 \\ 0 & 0 & 0 & h & c & 0 & 0 \\ 0 & 0 & f & 0 & 0 & 0 & 0 \end{bmatrix}$$

We can see the following principal submatrix and corresponding induced subgraph:

$$\begin{bmatrix} 0 & a & 0 & 0 & 0 & 0 & 0 \\ a & 0 & d & 0 & b & 0 & 0 \\ 0 & d & 0 & g & 0 & 0 & f \\ 0 & 0 & g & 0 & e & h & 0 \\ 0 & b & 0 & e & 0 & c & 0 \\ 0 & 0 & f & 0 & 0 & 0 & 0 \end{bmatrix}$$

As well, we see the following principal submatrix of an independent set of the graph:

$$\begin{bmatrix} 0 & a & 0 & 0 & 0 & 0 & 0 \\ a & 0 & d & 0 & b & 0 & 0 \\ 0 & d & 0 & g & 0 & 0 & f \\ 0 & 0 & g & 0 & e & h & 0 \\ 0 & b & 0 & e & 0 & c & 0 \\ 0 & 0 & 0 & h & c & 0 & 0 \\ 0 & 0 & f & 0 & 0 & 0 & 0 \end{bmatrix}$$

Now to prove the Cvetković Bound:

#### 1.2 Theorem.

**Cvetković Bound** — Let G be a graph on n vertices, and W be the weight matrix of G. Then the following inequality holds:

$$\alpha(G) \le \min\{|G| - n_+(W), |G| - n_-(W)\}$$
(3)

*Proof.* <sup>1</sup> Let H be the subgraph of G formed by the vertices in an independent set of size s. Then H is an induced subgraph of G and all eigenvalues of the principal submatrix W(H) are 0 since the principal submatrix will just be a zero matrix. Let  $\lambda_i$  denote the ith largest eigenvalue of W and  $\tau_i$  denote the ith largest eigenvalue of W and v0 denote the v1 largest eigenvalue of v2. Now, by interlacing, we have,

$$\lambda_i \ge \tau_i = 0 \text{ for all i } \in \{1, \dots, s\}$$
 (4)

and so

$$n - n_{-}(W) = n_{+}(W) + n_{0}(W) \ge s \tag{5}$$

Also, note that by negating W, the positive eigenvalues become negative eigenvalues and vice versa. Thus,

$$n - n_{+}(W) = n - n_{-}(-W), \tag{6}$$

 $<sup>^1\</sup>mathrm{Interesting}$  Graphs and their Colourings, unpublished lecture notes C. Godsil (2004)

However, the principal submatrix corresponding to H in -W is still the zero matrix and thus has all zero eigenvalues. Thus, by interlacing, we get a similar result as above,

$$n - n_{+}(W) = n - n_{-}(-W) = n_{+}(-W) + n_{0}(-W) \ge s \tag{7}$$

Therefore, both  $n - n_+(W)$  and  $n - n_-(W)$  are greater than or equal to s. Since s is the size of the idependent set, we can see that letting  $s = \alpha(G)$ , we get:

$$\alpha(G) \le \min\{|G| - n_+(W), |G| - n_-(W)\} \tag{8}$$

1.2 Graphs with Tight Inertia Bounds

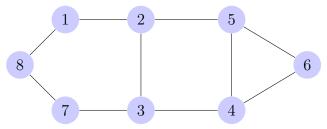

#### 1.2.1 Perfect Graphs

#### 1.5 Definition.

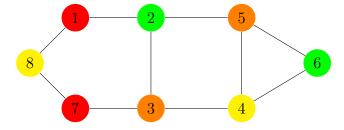

**Chromatic Number** — The chromatic number of a graph,  $\chi(G)$ , is the minimum number of colours needed in a proper colouring of G. [1]

#### 1.3 Example.

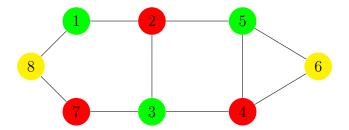

Consider the following graph:

An example of a colouring would be:

However,  $\chi(G)$  for this graph is 3:

#### 1.6 Definition.

Clique — An m-clique in a graph is a complete subgraph on m vertices. [1] The clique number,  $\omega(G)$ , is the number of vertices in a maximum clique of G.

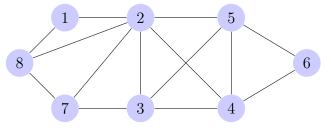

#### 1.7 Definition.

Clique Cover — A Clique Cover of the vertex set V(G) of a graph G is a set of cliques C, such that each vertex is in at least one clique in C.

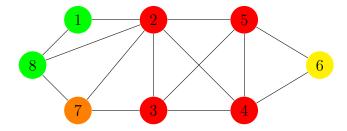

The clique cover number,  $\theta(G)$  is the minimum number of cliques needed in a clique cover of G. [1]

#### 1.4 Example.

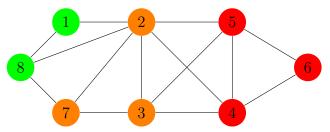

Consider the following graph:

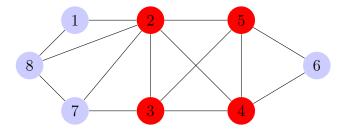

A possible clique covering is:

However, we can find that  $\theta(G)$  is equal to 3 (smallest I could find):

As well, the clique number,  $\omega(G)$ , is 4:

#### 1.8 Definition.

**Perfect Graph** — A graph G is perfect if  $\chi(G) = \omega(G)$  for all induced subgraphs, H, of G.

### 1.2.2 Graphs with an Eigensharp decomposition by Stars

## 1.3 Other Bounds on Independence Number

## 2 Algorithm to Find Graphs Lacking a Tight Inertia Bound

## 2.1 Outline of Method

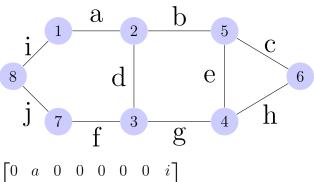

#### 2.1 Definition.

**Optimal Weight Matrix** — A weight matrix, W, of a graph, G, is optimal if

$$\alpha(G) = \min\{|G| - n_{+}(W), |G| - n_{-}(W)\}$$
(9)

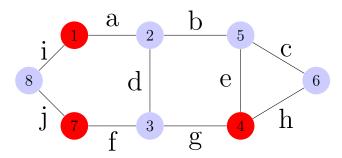

#### 2.1 Example.

Consider the following graph, G, with corresponding weight matrix W:

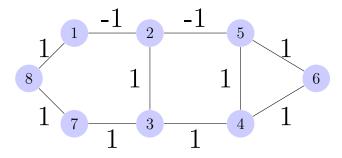

$$\begin{bmatrix} 0 & a & 0 & 0 & 0 & 0 & 0 & i \\ a & 0 & d & 0 & b & 0 & 0 & 0 \\ 0 & d & 0 & g & 0 & 0 & f & 0 \\ 0 & 0 & g & 0 & e & h & 0 & 0 \\ 0 & b & 0 & e & 0 & c & 0 & 0 \\ 0 & 0 & f & 0 & 0 & 0 & 0 & j \\ i & 0 & 0 & 0 & 0 & 0 & j & 0 \end{bmatrix}$$

We can see the independent number of G is 3:

Now, let G have the following weighting:

$$\begin{bmatrix} 0 & -1 & 0 & 0 & 0 & 0 & 0 & 1 \\ -1 & 0 & 1 & 0 & -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 & 0 & 0 \\ 0 & -1 & 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

Finding the eigenvalues of W, we find there are 3 positive eigenvalues and 5 negative eigenvalues. Thus, we see for this weight matrix we have:

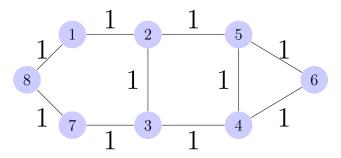

$$\alpha(G) = \min\{|G| - n_{+}(W), |G| - n_{-}(W)\}$$

$$= \min\{8 - 3, 8 - 5\}$$

$$= \min\{5, 3\}$$

$$= 3$$
(10)

Therefore, this is an optimal weight matrix of G. Now consider the following weighting for the same graph:

$$\begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

Finding the eigenvalues of this weight matrix, we find there are 4 positive

eigenvalues and 4 negative eigenvalues. Thus, we see we get:

$$\alpha(G) = 3 \neq \min\{|G| - n_{+}(W), |G| - n_{-}(W)\}$$

$$= \min\{8 - 4, 8 - 4\}$$

$$= \min\{4, 4\}$$

$$= 4$$
(11)

Therefore, we see that the previous weighting was not optimal for G.

#### 2.1 Lemma.

If a graph, G, with weight matrix W, has two induced subgraphs,  $S_1$  and  $S_2$ , such that  $S_1$  has  $\alpha(G) + 1$  positive eigenvalues under the weighting of W, and  $S_2$  has  $\alpha(G) + 1$  negative eigenvalues under the weighting of W, then W is not optimal

$$\square$$

# 2.2 Preliminary Tests to Determine if the Graph may be Suitable

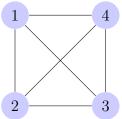

#### 2.2.1 Test for $\alpha$ -Critical

#### 2.2 Definition.

 $\alpha$ -Critical — A graph, G, is  $\alpha$ -critical if  $\alpha(G) < \alpha(G-e)$  for all edges e.

#### 2.2 Example.

Consider the following graph G:

we see that  $\alpha(G) = 1$ . But since this graph is complete, we see that if we delete any edge, we can get an independent set of size 2 by making the set include the two vertices that were connected by the edge we deleted. For example:

Thus, G is  $\alpha$ -critical.

#### 2.2 Lemma.

If G is  $\alpha$ -critical, and W an optimal weight matrix of G, then  $w_{i,j} \neq 0$  for all  $i, j \in E(G)$ 

*Proof.* Assume for the sake of contradiction, that for some  $i, j \in E(G)$ , we have  $w_{i,j} = 0$ . Then, we know  $\alpha(G - e_{i,j}) > \alpha(G)$  because G is  $\alpha$ -critical. Thus:

$$\alpha(G) < \alpha(G - e_{i,j}) \le \min\{|G| - n_+(W), |G| - n_-(W)\}$$

Thus, we see that the inertia bound is not tight for G, so W is not an optimal weight matrix of G, which is a contradiction.

Due to the complexity of needing to consider edges that could potentially be zero in the weight matrix, it is easier to consider graphs that are restricted to only non-zero edge weights in its optimal weight matrix. Thus, it makes sense to only consider  $\alpha$ -critical graphs, because of Lemma 2.2 ensuring that all  $\alpha$ -critical graphs have non-zero weight matrices.

#### 2.2.2 Determining Each Triangle Must Have the Same Sign
